Strategies for uncovering hidden value in retirement income planning

A cautionary tale

A client came to us as he was retiring at age 78. He had $5 million in a qualified plan, so he was confident that he would never run out of money. But due to inattentive planning, he was paying more tax than was necessary.

The client’s required minimum distributions (RMDs) and other income were generating more than $250,000 a year, but he was living on far less, meaning he was in a higher tax bracket than his lifestyle dictated. Furthermore, this resulted in unnecessary Medicare surcharges and taxes on his Social Security benefits.

Before those RMDs kicked in, he could have taken action to make sure they wouldn’t be more than he needed, such as converting qualified funds into a Roth IRA, buying life insurance (he’s uninsurable now) or purchasing an inheritable annuity. If he had harbored some of his money in investments that don’t have RMDs, he wouldn’t be paying so much income tax.

Yes, he has enough money to live comfortably, but he’ll be passing on tax-depleted assets to his heirs. That’s because his RMDs are being taxed before they’re reinvested. If conversions to non-RMD financial vehicles had happened earlier, that growth could have been tax free (in the case of a Roth investment) or no RMD would be required at all, so growth would continue to compound.

This white paper explores how an understanding of tax efficiency in retirement can help you bring a new perspective to your conversations with clients about retirement income planning.
The need for a tax-efficient spending plan

In the latest Nationwide Retirement Institute Tax and Retirement Survey,1 50% of consumers polled said they think taxes will stay the same in retirement, 34% think they'll decrease and 16% think they'll increase. Needless to say, no one knows the future of tax policy, so it’s understandable that there is a range of opinions.

What we do know is that the burden of saving for retirement has shifted to the individual.

According to the same retirement survey, 27% of future retirees say their primary source of retirement income will be an employer-sponsored retirement account (vs. 4% of those recently retired and 7% percent of those retired more than 10 years).1

In addition, as the employment landscape changes and more people find work as contractors, fewer individuals may have access to employer-sponsored retirement plans. These workers need to take the initiative to save for retirement with accounts such as traditional IRAs.

But no matter what their primary source of income, it’s important for retirees to have tax-diverse investments so that money can be withdrawn efficiently, according to whatever tax laws are in place during their retirement.

A tax-efficient spending plan—the order in which clients choose to tap into their savings to fund their income needs—can give clients the assurance that their money can last through their retirement years. It’s important to explore alternatives to what clients typically practice (the common “file and collect Social Security benefits first” spending model).

The Nationwide Retirement Institute is pleased to be your partner. Look to us for resources, tools and fresh takes on retirement planning so your clients can continue to look to you for solutions.

Covisum President Joe Elsasser contributed technical content and scenarios to illustrate the tax-efficiency strategies discussed herein.

Shift your clients’ perspectives on retirement income planning

Your clients look to you for expertise and advice as they transition to their retirement years. Guiding them to a sound retirement income strategy is one of many opportunities you have to help them live the life they’ve imagined.

Retirement income planning often takes a predictable approach: Claim Social Security benefits as early as possible, and when additional income is needed, liquidate investments with the lowest tax impact first. Generally, this means using any nonqualified funds first and reserving qualified funds (such as money in IRAs and 401(k)s) for later in retirement or taking only required minimum distributions (RMDs) from those accounts.

As a growing body of research illustrates the importance of Social Security benefits to a retirement income plan, more clients are opting to use — the best sequence of spending to follow — to meet income needs during the Social Security delay.

Economists John Shoven and Sita Slavov suggest that retirees are often considerably better off using qualified assets, such as IRA or 401(k) funds, to bridge the gap during a period of Social Security delay.2

Another pair of economists, Huaxiong Huang and Moshe Milevsky, argue that in the presence of differential tax rates, people should intentionally deplete certain assets sooner in retirement while saving other assets for later in retirement.3 Both papers suggest that few clients are evaluating sequencing options as they make retirement income decisions.

Advisors who can offer a practical process for evaluating spending decisions from a holistic perspective can deepen relationships by providing clients with the assurance that their assets are working together to help them achieve their retirement goals.

---

The tax differential among alternate sequences of spending can be significant, and the potential lies in looking beyond account- and product-level taxation.

Many advisors acquire a knowledge base on taxation through the course of their practice, whether formal or practical; yet their understanding tends to be in the context of a specific account or product. They know a CD pays interest that is treated as ordinary income, and when they sell a stock or a mutual fund, they will probably incur a short- or long-term capital gain or loss. Advisors also learn about account-level taxation. Assuming certain holding periods and age limits, withdrawals from a Roth IRA are tax free, and withdrawals from a fully deductible traditional IRA will be treated as taxable ordinary income. If they sell a stock inside the account and withdraw the funds, the withdrawal gets account-level (rather than product-level) tax treatment.

What practical experience typically fails to deliver is an understanding of the implications of interactions among income sources. What does an IRA withdrawal do to the taxability of a capital gain? What does the presence of capital gains do to the taxation of Social Security benefits? And how is the client’s effective tax rate impacted when he or she has all of the above? The first two questions are examples of product- and account-level tax considerations; the third points to the importance of a deeper awareness of interactions.

An IRA withdrawal alone rarely creates a tax surprise for a client. Instead, it is the IRA withdrawal (or the phaseout of a medical expense deduction or the introduction of a net investment income tax) and its interaction with capital gains and Social Security. Therefore, it is important to consider the full picture when making financial decisions.

### Three common sequencing options

#### 1. CAPITAL GAINS + IRA

Consider long-term capital gains, which are taxed at 0% when the taxpayer’s ordinary income plus capital gain falls under certain thresholds: 15% for most taxpayers and 20% for the highest-income taxpayers.

In 2020, a married couple filing jointly and over age 65 has a standard deduction of $27,400 (i.e., the normal deduction of $24,800 plus $1,300 each for being over 65). If this couple takes $107,400 in long-term capital gains and has no other income, they would pay no federal income tax.

```
<table>
<thead>
<tr>
<th>INCOME (IN THOUSANDS)</th>
<th>0% tax on capital gains up to $80,000</th>
<th>15% tax on capital gains above $80,000</th>
</tr>
</thead>
<tbody>
<tr>
<td>$107,400</td>
<td>$0</td>
<td>$10,000</td>
</tr>
</tbody>
</table>
```

Another scenario: Withdrawing $10,000 from an IRA

Now consider this: If the same couple took an additional $10,000 from an IRA, they would pay no ordinary income tax, because the ordinary income would be eliminated by the standard deduction. However, the $10,000 withdrawal would push $10,000 of capital gains into the taxable range at 15%.

The client’s tax software or return summary from most major tax preparation firms will show the client in a 0% tax bracket, yet the effective tax rate is 15%.

```
<table>
<thead>
<tr>
<th>INCOME (IN THOUSANDS)</th>
<th>$10,000 from IRA</th>
<th>$80,000 of standard deduction</th>
</tr>
</thead>
<tbody>
<tr>
<td>$0</td>
<td>$10,000 x15%</td>
<td>$80,000 x0%</td>
</tr>
<tr>
<td>$107,400</td>
<td>$107,400</td>
<td></td>
</tr>
</tbody>
</table>
```

The scenarios discussed in this white paper are hypothetical and for illustrative purposes only; results may differ. Nationwide and its representatives do not provide tax or legal advice. Clients should consult their attorney or tax advisor for such advice or for answers to their specific questions. This paper does not constitute legal or investment advice. Please consult with your tax or legal advisor.
Let’s consider another example that’s quite common, in which we combine a Social Security benefit with IRA withdrawals. In the absence of any other income, Social Security benefits at current levels will not trigger federal income tax; however, the presence of other income causes the Social Security benefit to become taxable income.4

For this example, we have a married couple, both over age 65, who take $20,000 from an IRA to supplement their combined $50,000 Social Security benefit. Because they are over 65, their standard deduction is $27,400.

Because they are now combining other income with their Social Security benefits, we must calculate their provisional income and taxable Social Security income before we apply the standard deduction.

It’s possible that these calculations have not been part of your advisory duties before now, but it’s important to understand them as part of understanding the tax efficiency story. The provisional income (sometimes called “combined income”) in this case is the IRA withdrawal plus half of the Social Security income. That’s $45,000.

Then we use that figure to calculate how much of the Social Security income is taxable.5 Up to $32,000, provisional income is multiplied by zero. Provisional income between $32,000 and $44,000 ($12,000) is multiplied by 50% ($6,000). Provisional income above $44,000 (in this case, $1,000) is multiplied by 85% ($850). Therefore, the math reveals that they have $6,850 of taxable Social Security income.

Now we add the IRA withdrawal to that, bringing their total AGI to $26,850. That is less than their standard deduction, so no tax is owed.

Another scenario: Withdrawing an additional $10,000 from an IRA

But suppose this couple decides to withdraw an extra $10,000 from their IRA to fund a dream vacation — expecting, at worst, to lose 10% on part of their withdrawal to federal income tax. They believe this because they currently pay no tax, and an IRA withdrawal is taxed as ordinary income. Therefore, if an extra $10,000 pushes them into a taxable scenario, it would be in that first marginal tax bracket, which is 10%. It’s a reasonable thought, but unfortunately it’s not correct. Here’s why:

In this case, an extra $10,000 from an IRA would affect their provisional income, and that triggers other effects.

Notice that their provisional income would become $55,000 (rather than the previous $45,000). In turn, this means their taxable Social Security income would be $15,350. Add that to the IRA withdrawal that’s now $30,000, and you get an AGI of $45,350. When you apply their standard deduction of $27,400, you’re left with taxable ordinary income of $17,950. This taxable income would indeed be taxed at the 10% rate as they expected, for a tax bill of $1,795. But notice that the effective tax rate on the extra $10,000 is actually 17.95% ($1,795/$10,000).

Why would this couple jump directly from a 0% tax rate on their first $70,000 of gross income to a nearly 18% rate on the next $10,000? The reason for the jump is the interaction between IRA withdrawals and Social Security income. Because of the increase in provisional income, there is an increase in the amount of taxable Social Security income. In this case, the $10,000 of extra provisional income leads to an $8,500 increase in taxable Social Security income.

5 For details on how provisional/combined income is taxed, visit https://www.ssa.gov/planners/taxes.html.
Now let’s consider a scenario with income from three sources: Social Security, IRA withdrawals and capital gains. A couple, both over age 65, have $60,000 in combined Social Security benefits, $41,000 in annual IRA withdrawals and $20,000 in long-term capital gains.

Because there are other income sources besides Social Security, we need to calculate provisional income, which is $91,000. That figure helps us calculate taxable Social Security income, which is $45,950.

From here, we first determine the ordinary income by adding the taxable Social Security to the IRA withdrawals. That gets us to $86,950 — and this is the point when we apply the standard deduction. This reveals that the couple’s taxable ordinary income is $59,550.

Let’s pause here to calculate their ordinary income tax. In this scenario, they owe $6,751 for an effective tax rate of 11.3%.

The next step is to add the long-term capital gains to the taxable ordinary income. Doing that delivers a figure of $79,550, which is less than the capital gains tax threshold of $80,000. Therefore, the capital gains tax is zero.

But what if that same couple takes an additional $5,000 IRA withdrawal?
Another scenario: How an additional $5,000 withdrawal could be taxed at 48%

But if this same couple were to take an extra $5,000 IRA withdrawal, they would pay an extra $2,430 in tax, giving them an effective tax rate on the withdrawal of 48% ($2,430/$5,000). Here’s how that would happen:

+ The $5,000 IRA withdrawal increases their provisional income
+ The higher provisional income results in more of their Social Security dollars being taxable, pushing up their ordinary income
+ A portion ($8,800) of the long-term capital gains is pushed above the $80,000 threshold and is taxable at 15%

If we now calculate the taxes, we see that the ordinary income tax is $7,861, an effective tax rate of 11.4% — not so different from the other scenario.

But there are capital gains taxes, too, which come out to $1,320.

That yields a total tax bill of $9,181, which is $2,430 more than the previous year. When a $5,000 withdrawal results in $2,430 of additional taxes, that’s an effective tax rate of 48% on the withdrawal.
Common sequences of spending every advisor should know

Product interactions with tax implications are relatively common and often highly impactful. It’s easy to see how careful consideration of the sequence of spending can add substantial value to the client’s spendable income.

Few clients will be willing to plan on a year-to-year basis; they’ll want the assurance of knowing that their money will last, and they’ll want to feel prepared — so it may be useful to establish a spending plan that is thoughtfully constructed and that retains flexibility for occasional modifications.

The right strategy is personal and based on the client’s goal

So how can you determine which strategy is best for your client? You can certainly assess the impact on your client’s total tax bill. You should also consider how each scenario contributes to your client’s financial well-being.

For most clients, this means supporting one of three goals:

1. Extending the life of their retirement portfolio (portfolio longevity)
2. Maintaining their standard of living in retirement (sustainable income)
3. Preserving savings to pass on to heirs (after-tax estate value)

We’ll use these common goals to compare the Social-Security-first sequence against the other sequences of spending to see which could deliver a higher value. To illustrate, let’s apply our three sequences of spending to a hypothetical client.

---

**Three basic sequences of spending to consider**

**Social Security first**
The most common sequence, in which Social Security is claimed as early as possible, either due to retirement or attainment of age 62. Nonqualified assets are used to supplement the Social Security benefit for as long as possible, and qualified assets are accessed as required to meet RMDs at age 72 or for needed income.

**IRA first**
An increasingly popular sequence in which Social Security benefits are delayed and qualified funds are used to provide income during the delay. Any nonqualified funds are reserved for future needs.

**Roth conversion**
A less common sequence in which Social Security benefits are delayed and annual Roth conversions are considered to the extent they can be completed without increasing the client’s effective marginal tax rate under the Social-Security-first model. Spending during the delay and any additional taxes resulting from the conversions are paid from nonqualified assets for as long as possible. Qualified funds are likely to be needed at age 72 to meet RMDs.
Putting the three spending sequences to the test

John and Jane are 65 and 62, respectively. John has saved $650,000 in his 401(k) plan. John’s primary insurance amount (PIA) — the Social Security benefit he would receive at full retirement age — is $2,600 per month. Jane has a $200,000 IRA and an $1,100 PIA. They have $400,000 in a joint brokerage account with a basis of $300,000, and they are planning for life expectancies of 90 for John and 95 for Jane. They need an after-tax income of $6,000 per month in retirement and $5,000 for the survivor.

If they follow the traditional Social-Security-first sequence of spending, John and Jane can expect to be able to meet all of their spending goals with a significant surplus at Jane’s death.

**Explanation:** The purple bars are the net spendable income after federal income tax. The gray is the amount paid in federal income tax and the yellow line is the after-tax spending need. Ideally, the purple bar will extend to the yellow need line for all years of retirement (and even in alternate scenarios in which the plan is stressed by changes in the investment markets, an untimely death or a long-term care event).

For the first several years of retirement, John and Jane would pay no federal income tax. In all likelihood, they are thrilled, but when advisors see this — particularly when there are large IRAs that will force RMDs later — they should be wary. Note how the purple bar extends above the spending need line once John reaches age 72. This could signify that a different sequence of spending may be beneficial to avoid pushing clients into higher tax brackets in the future.

**Here’s what John and Jane’s account balances look like over time after accounting for their income withdrawals. You can see their balances growing throughout their lifetimes.**

John and Jane are probably ideal clients for many advisors. If they follow the traditional Social-Security-first sequence of spending, they will be fine.

Many would say they don’t need an advisor; however, a well-trained advisor could use this analysis to identify significant value for this client.

For John and Jane, the traditional Social-Security-first sequence of spending generates a net after-tax estate value of roughly $838,762 with approximately $324,359 in lifetime taxes paid.

---

*The cost-of-living adjustment (COLA) is assumed to be 2.6% annually.*
Now let’s consider an alternate sequence of spending in which John and Jane implement an IRA-first strategy. This scenario assumes that Jane claims her Social Security benefit at her full retirement age of 66 years and 8 months. Later, she adds her spousal excess at age 67 when John claims his Social Security benefit at age 70.

As a result of applying an IRA-first strategy, we see a $97,871 net increase in the after-tax estate value and a $11,072 decrease in the present value of lifetime taxes paid. The net increase in the estate value is partially due to the tax reduction and partially due to the more effective use of Social Security as part of the plan.

Notice that taxes are more evenly disbursed throughout retirement. In the early years, John and Jane are paying some federal income tax, but also note that the RMDs forced from the IRAs at age 72 are considerably smaller.

Here’s what their account balances look like over time after accounting for their income withdrawals. In this case, the nonqualified account has been allowed to grow throughout the clients’ lifetime, primarily leaving to beneficiaries assets that will receive a step up in basis, resulting in very little net income tax to the beneficiaries.
A third potential sequence of spending incorporates the same Social Security strategy but uses the clients’ nonqualified funds to bridge the gap until Social Security benefits begin. We also identify strategic opportunities to convert portions of the clients’ traditional IRAs to Roth IRAs. In this strategy, the older client’s traditional IRAs are converted first to provide the maximum reduction in the couple’s eventual RMDs.

To do this, we annually determine how much could be converted to Roth to the extent the rate we would pay to do a Roth conversion is lower than the clients’ expected tax rate if they followed the traditional harvesting pattern. If it is lower and nonqualified funds are available to pay the tax on the conversion, then we convert only enough IRA to fill that tax bucket.

For example, a married couple filing jointly with $60,000 in ordinary income could convert up to $20,250 into a Roth and stay within their tax bracket.

You could consider this the “first do no harm” method for identifying Roth conversions. Although more aggressive Roth conversion strategies may yield higher lifetime benefits, this strategy considers the possibility that tax rates or structures may change in the future, making Roth IRAs less attractive than they are in the current tax environment.

Let’s examine how this idea would work for John and Jane. Incorporating Roth conversions into this sequence of spending produces approximately $127,024 of additional after-tax estate value — nearly a 15% increase over the traditional harvesting pattern — while reducing taxes by approximately $67,873.

First, let’s look at the “before Roth conversions” projection. You can see John and Jane are drawing heavily from the nonqualified account early on in order to delay John’s larger Social Security benefit. Then you see the IRA RMDs kick in. The couple’s financial advisor may recommend that they instead convert some funds to a Roth. Then the plan is to make no Roth withdrawals, effectively allowing the Roth assets to compound tax free over the entire retirement period.

The conversion amounts grow for the first few years, then become smaller over time. You’ll see this on the next page.

2020...$38,565.20  2022... $43,584.51  2024... $28,491.88  2026... $18,260.66
2021....$41,263.89  2023.... $47,733.59  2025.... $18,728.29

Calculations reflect conversion costs based on tax rates at the time of the conversion. Projected tax brackets assume a 2.6% annual increase.
By the end of the projection period, the Roth assets would have grown to almost $1.5 million. When the survivor (Jane) dies, her beneficiaries will be required to take RMDs from the inherited Roth, but the 10% tax penalty doesn’t apply to any beneficiary distribution. Distributions of earnings to the beneficiary may be income-tax free if it has been more than five years from the first owner’s funding of the Roth IRA. This may provide significant additional tax-free growth potential and tax-free income. For those with large estates, the transfer may be subject to estate taxes.

In this example, we maintained equal asset allocations across all accounts. If we locate the highest growth assets in the Roth instead of the equal allocation, the benefits of the conversion strategy would be considerably higher. The conversion amounts allowed the clients to “fill up” the 10% tax bracket. Therefore, from a tax perspective, you notice there is still very little tax owed in early retirement.
The power of an objective framework

Working through the details of John and Jane’s situation should not suggest that all clients follow a Roth conversion strategy. Nationwide offers another white paper that discusses when Roth conversions may be suitable.

The examples shown here are intended to highlight a process that may be used to evaluate multiple sequences of spending for any client. For many, the IRA-first strategy will be more impactful. For some, the traditional Social-Security-first sequence will offer the greatest benefit. Ultimately, advisors should evaluate the options through a consistent and objective framework.

A strategic spending plan can have a significant impact on clients’ ability to achieve their desired lifestyle in retirement and to leave a financial legacy to the people or causes they care about.

Advisors who incorporate tools to identify and implement sequence of spending options for their clients stand to grow their business and differentiate themselves as retirement income specialists.
